

ED response plan description

The plain-language situation Priya hands to AI in the demo, the raw material AI turns into the response plan table and log.

Priya's plain-language description

Every morning we look at a control chart of the average time it takes a patient to be seen by a doctor in our emergency department. The lead charge nurse is the one who checks it. We treat it as a signal if any point lands outside the limits, or if eight points in a row sit on one side of the center line. When that happens, I want the lead charge nurse to look into the cause, starting by checking whether the procedure we wrote for getting admitted patients a room upstairs is actually being followed, then tell the ED operations manager, write down what they found and what they did about it, and confirm the chart settles back to normal.

What this already contains: what and how often (the door-to-doctor chart, checked every morning); owner (the lead charge nurse); the signal rule (any point outside the limits, or eight points in a row on one side); the first steps (investigate via the room-request procedure, escalate to the ED operations manager, log it, confirm the chart settles). All of this is human knowledge AI cannot invent; it can only structure what Priya already knows.
