

Divergent and convergent cards

The two demo prompts: the first opens the problem up wide, the second turns the AI into a skeptic to stress test your chosen option before you spend a cent.

The prompt

Divergent (brainstorm a range)

You are a Lean Six Sigma expert. I am a white belt. Our root cause is this. When a patient is admitted to the hospital from the emergency department, no one is clearly in charge of arranging their room upstairs, so they get stuck waiting in an emergency department bed, which fills up the department and makes new patients wait longer to be seen. Brainstorm a range of possible solutions, from very simple and low tech to more complex, and for each note roughly how much effort it would take.

Convergent (skeptical stress test)

Act as a skeptical ED operations manager. Here is my proposed solution, naming a charge nurse each shift to own the bed request. Tell me every way this could fail or backfire in practice.

What good output looks like

The divergent prompt returns a useful spread from simple to complex: name a charge nurse each shift who owns initiating the bed request the moment an admit decision is made; a twice-daily bed huddle between the ED and inpatient units; a visual board showing which admitted patients are waiting and for how long; and at the heavy end, an automated bed management system. The convergent prompt makes the AI turn against the simple front runner and surface real failure modes: what happens at shift change when the owner hands off, what if the charge nurse is slammed with a critical patient, what if the inpatient units simply have no beds. Priya uses those failure modes to harden the simple solution (a backup owner, logging the bed request the moment the admit decision is made) rather than jumping to the expensive system. The machine expands and challenges; Priya decides.
